Epistemic Modals and Information-State-Sensitive Evaluation

1. The Demand on an Adequate Account

The stated demand is that an adequate semantics of epistemic modals make modal evaluation sensitive to information states, not only to worlds. The conclusion states what an adequate account must take into consideration: information states must matter to modal evaluation, not only worlds. The stated demand is not world-only evaluation; it requires modal evaluation to be sensitive to information states as well. It is a demand on the account, not a claim here that the account has been independently established.

The proposal is supported by two stated commitments. Dynamic semantics gives conjunction a sequential interpretation and treats the might-operator as a consistency test (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). In the example, the not-raining information is added before the might-information; the resulting consistency contrast is with the reverse order, which presents no problem. Accordingly, order matters in discourse (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). These are the grounds for the demand, rather than additional conclusions about every epistemic modal.

The relevance of the commitments can be stated in their exact terms. The stated commitments and order contrast support the conclusion: might tests consistency on an information state, and the different sequence changes whether the might-claim remains consistent. The contrast is therefore presented as evidence that epistemic-modal evaluation is information-state-sensitive: the consistency test is applied against an information state, and the sequential interpretation makes order matter to that state (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

On those commitments and that contrast, the account is required to make modal evaluation sensitive to information states, not only to worlds (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). In the example's sequential-addition contrast, the not-raining information is added before the might-information; in the reverse order, the sequence presents no problem. The supplied order effect supports the demand that modal evaluation be sensitive to information states, not only to worlds. This states the direction of support: the commitments and the example support the requirement. It does not assert that the requirement proves the commitments independently, or that the example establishes a universal account of all epistemic modals.

The scope of the demand remains the one expressed in the conclusion. The conclusion states that an adequate account must make modal evaluation sensitive to information states, rather than relying on worlds alone. For this argument, the relevant points are sequential conjunction, consistency-testing might, and the different outcomes for the two orders of the raining information. The claim is a requirement for adequacy, supported by the stated commitments and contrast; the example alone does

not establish that every epistemic modal behaves this way. The example supports the proposal; it does not by itself establish that every epistemic modal behaves in this way (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The stated demand concerns what an adequate semantics of epistemic modals must include in evaluating them: sensitivity to information states, not only to worlds. The conclusion requires sensitivity to information states, not exclusive reliance on worlds. The conclusion requires information states to matter to modal evaluation; it does not state a world-only basis. The claim is about adequacy: it specifies a condition the account must meet, rather than reporting that this condition has been independently established (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The proposal's support stays tied to the two commitments and the order contrast already stated. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the two features at issue. In the example, the not-raining information is added before the might-information; the resulting consistency contrast is with the reverse order, which presents no problem. The demand follows as the proposal supported by these commitments and this contrast, not as a claim that the example settles the behavior of every epistemic modal (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

For this argument, conjunction receives a sequential interpretation and might is treated as a consistency test; these are the stated features under consideration. In the example, the not-raining information is added before the might-information; the reverse order presents no problem. These are the terms in which the contrast bears on evaluation: it concerns consistency following the addition of information, rather than an order-free description of the two items (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

Accordingly, the supplied commitments and contrast support the adequacy condition that modal evaluation be sensitive to information states, not only to worlds. The conclusion requires information-state sensitivity, while its wording does not say that worlds have no role. The conclusion requires information-state-sensitive evaluation rather than a world-only account; this states the supplied demand without adding a further claim. This restatement preserves the direction of support, from the commitments and the described order effect to the requirement on an adequate account (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The example's stated role and limit belong together. The example supports the proposal's claim: the commitments and order contrast support information-state-sensitive modal evaluation, though not a universal claim about all epistemic modals. Yet the contrast does not by itself establish that every epistemic modal behaves in that way. The conclusion remains the narrower demand on an adequate semantics, supported by the stated commitments and contrast, rather than a universal claim. It should not be recast as a universal claim about every epistemic modal, or as an independently established fact. On the supplied support, information states must matter to evaluation, while the example's reach remains limited to its role in supporting that requirement (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

2. Sequential Conjunction and Consistency Testing

The semantic commitments at issue are that dynamic semantics gives conjunction a sequential interpretation and interprets the might-operator as a consistency test (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the two features being considered. The account under consideration pairs sequential conjunction with consistency-testing might; stated more fully, it treats conjunction sequentially and might as a consistency test.

For this argument, conjunction receives a sequential interpretation; this sentence states that feature without drawing out any consequence. For this argument, conjunction receives a sequential interpretation; the point here is simply the sequential treatment of conjunction. This commitment specifies how conjunction is handled, without requiring any further claim about the consequences of a particular ordering. It supplies the sequential part of the proposal as stated (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

For this argument, the might-operator is treated as a consistency test; this sentence states that feature without adding a further consequence. For this argument, the might-operator is characterized as a consistency test; no further details of its operation are needed here. The operator’s stated role is a consistency test; the commitment does not require a claim about some other function of might. This gives the modal evaluation an explicit relation to information: the relevant question is whether the might-claim remains consistent with the information state (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The two commitments can be set out separately while keeping their joint role in view. For this argument, the sequential interpretation concerns conjunction, while the consistency-test treatment concerns might; these are the two features under consideration. For this argument, the first feature is sequential conjunction and the second is consistency-testing might; this is the pairing under consideration. Neither commitment needs to be enlarged to state the combination: the account gives conjunction a sequential interpretation and treats might as a consistency test (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; no further consequence is asserted here. For this argument, the might-operator is treated as a consistency test; this sentence states only that feature of the account. For this argument, conjunction receives a sequential interpretation; this sentence states only that feature of the account. For this argument, conjunction receives a sequential interpretation and might is treated as a consistency test; these are the two features under consideration. These are the semantic commitments being explained here, not additional conclusions about every modal expression or about other properties of conjunction (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

For this argument, the might-operator is treated as a consistency test; this restates the feature at issue without extending it. For this argument, the role assigned to might is that of a consistency test; no further role is asserted here. For this argument, conjunction is interpreted sequentially; this states the

treatment at issue without adding a further rule. The two commitments together describe how the account frames epistemic-modal claims: a sequence is part of conjunction's interpretation, and consistency with information is part of might's interpretation (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The scope here remains limited to those supplied commitments. Dynamic semantics gives conjunction a sequential interpretation and interprets might as a consistency test (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). The supplied commitments are sequential conjunction and consistency-testing might; this restates them without adding another semantic rule. Nor does the account, as presented in these commitments, specify a broader claim about all epistemic modals. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; this states the pairing without a broader claim about all epistemic modals.

For this argument, the two features are distinct: a sequential interpretation of conjunction and a consistency-test treatment of might. For this argument, conjunction receives a sequential interpretation; this sentence states that feature and does not add another semantic rule. For this argument, the might-operator is treated as a consistency test; this sentence states that feature and does not add another semantic rule. Keeping those roles distinct makes clear what each commitment contributes, without adding a further semantic rule or assigning either feature to a different operator. Together, they state how dynamic semantics treats conjunction and might (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

For this argument, the first feature is that conjunction receives a sequential interpretation; no further consequence is stated here. For this argument, the account treats conjunction sequentially; this restates the feature without specifying additional stages or outcomes. This restatement does not specify additional stages, outcomes, or rules for how any particular conjunct changes an information state. For this argument, the content at issue is a sequential interpretation of conjunction; this restates the feature without extending it. That is the first part of the stated semantic pairing (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

For this argument, the second feature is that might is treated as a consistency test; no further consequence is stated here. For this argument, might is treated as a consistency test; this restates the feature without specifying additional details of its operation. For this argument, consistency testing is the feature assigned to might; this sentence does not add another role or rule. For this argument, the two features are sequential conjunction and consistency-testing might; together they describe the pairing under consideration. Neither description needs an additional claim about other modal operators (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The supplied commitments identify conjunction as sequentially interpreted and the might-operator as a consistency test; they do not state a further rule. For this argument, the pairing under consideration is sequential conjunction and consistency-testing might; no additional feature is asserted. This explains the stated framing without extending it to a rule about every epistemic modal or to further consequences beyond the two commitments (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

Taken together, the proposal’s content remains exactly these two semantic commitments. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the two features at issue. For this argument, the two features are a sequential interpretation of conjunction and a consistency-test treatment of might. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the stated features under consideration. It is this limited pairing that frames the evaluation of epistemic-modal claims against information states (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

3. The Not-Raining Order Effect

In the example, the relevant point is the order in which information is added in discourse; this sentence does not extend the contrast beyond that example. In the order described, information that it is not raining is added before the information that it might be raining. In the example, information that it is not raining is added before the might-information; the stated result concerns their consistency in that order. The supplied contrast is therefore not simply between the two pieces of information considered without regard to sequence: it describes what happens when the information is added in one order (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The other order is the opposite order described in the contrast. In the example, the opposite order presents no problem; this sentence states only the reported outcome for that order. In the example, the outcomes differ by order: the not-raining-first sequence presents a consistency problem, while the reverse order presents no problem. The point is the difference between these two discourse orders, not a claim that the two orders have the same result (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The first part of the contrast can be stated narrowly. In the example, the first order adds information that it is not raining before the might-information; the stated result concerns that sequence. In the example, the stated consistency result concerns the might-information after information that it is not raining has been added. It does not require replacing the stated description with a broader conclusion about every possible order, every kind of information, or every epistemic modal. The example is specifically about the not-raining information and the information that it might be raining (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The reverse-order part should likewise be kept to its stated scope. In the example, the opposite order presents no problem; this sentence states only that outcome for the reverse sequence. In the example, the reverse-order outcome contrasts with the sequence in which the not-raining information is added first. The claim does not say more about what happens in the reverse order than that the sequence presents no problem; its role here is to mark the difference between the two orders. In this way, the example makes discourse order explicit without extending the contrast beyond the information supplied (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

In the example, the not-raining-first order raises a consistency problem for the might-information, while the opposite order presents no problem. In the example, the relevant contrast is between the sequences in which information is added in discourse; no broader order claim is made. The example’s

point can thus be restated without broadening it: in the specified pair of orders, whether the sequence presents a problem varies with which information comes first (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

In the example, the contrast between the two stated outcomes is summarized by the conclusion that order matters in discourse. In the example, the outcomes differ: the not-raining-first order raises a consistency problem for the might-information, while the opposite order presents no problem. names that contrast; it does not add a further outcome or a general rule beyond it. The claim remains tied to these two pieces of information and their two orders (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The example states a specific contrast between two orders of adding information. The example states a contrast between the two orders for the not-raining and might-be-raining information. The stated contrast distinguishes the order in which not-raining information is added from the opposite order. In the example, the not-raining-first order raises a consistency problem for the might-information; the opposite order presents no problem. These are the supplied terms of the order effect, and the conclusion that order matters stays within them (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The contrast can be separated into its two stated orders. In the first order described, information that it is not raining is added before information that it might be raining. In the example, the first order adds information that it is not raining before the might-information; the stated consistency result concerns that order. The supplied contrast attaches the stated consistency result to the not-raining-first order, and contrasts it with the opposite order. It does not state that the same result occurs without regard to which information is added first (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The opposite order supplies the other side of the contrast. In the example, the opposite order presents no problem; this states only the reported outcome for the reverse sequence. This clause does not specify some further outcome for that sequence; it says that the reverse order presents no problem. In the example, adding not-raining information before the might-information raises a consistency problem; the opposite order presents no problem. Both clauses are needed to express the supplied contrast between orders, without making either clause broader than its stated scope (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

In the example, the two stated outcomes are summarized by saying that order matters in discourse; no broader order claim is made. The stated contrast concerns the order in which the not-raining and might-information are added. It does not introduce another example or claim a result for other information, other sequences, or other modal expressions. In the example, the not-raining-first order raises a consistency problem for the might-information; in the reverse order there is no problem. Thus, the order effect is described through the contrasting results of these two sequences (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

Keeping the parts together preserves the proposition’s full content. In the example, the not-raining-first order raises a consistency problem for the might-information; in the opposite order there is no problem. In the example, the not-raining-first order raises a consistency problem for the might-information, while the opposite order presents no problem. In the example, each order has a different

stated outcome; this is the contrast summarized by saying that order matters in discourse. Restated narrowly, the supplied claim is that this contrast in adding the two specified pieces of information makes order matter in this discourse example (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

4. From the Contrast to Information-State Sensitivity

The conclusion is that an adequate semantics of epistemic modals must make modal evaluation sensitive to information states, not only to worlds. The stated commitments and order contrast support the requirement that modal evaluation be sensitive to information states, not only to worlds. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the two features at issue. The contrast is that after information that it is not raining is added, it is no longer consistent with information that it might be raining; in the opposite order, there is no problem, so order matters in discourse (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The connection begins with what the two semantic commitments specify. For this argument, the pairing under consideration is a sequential interpretation of conjunction and a consistency-test treatment of might. For this argument, might is treated as a consistency test; the example concerns the consistency of the might-information in the stated order. Stated this way, the commitments do not yet add a general conclusion about every epistemic modal. They specify the treatment of conjunction and might that is used to understand the supplied order contrast (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

In the example, the relevant point is the order in which information is added; this sentence does not extend the contrast beyond it. In the example, information that it is not raining is added before the might-information; the stated consistency result concerns that first order. In the example, the opposite order presents no problem; this sentence states only that outcome for the reverse sequence. In the example, adding not-raining information before the might-information raises a consistency problem; the opposite order presents no problem. in discourse in precisely this supplied sense (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The commitments make this contrast relevant to modal evaluation. The commitments support the conclusion: might tests consistency on an information state, and adding information in a different sequence changes whether the might-claim remains consistent. In the example, the not-raining-first order raises a consistency problem for the might-information; in the opposite order there is no problem. The stated commitments and contrast connect sequential conjunction and consistency-testing might with the order effect; they support information-state-sensitive evaluation. This is the stated route from the semantic commitments to the observed contrast (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The support for the conclusion follows that route. The stated commitments and order contrast support information-state-sensitive modal evaluation, rather than evaluation by worlds alone. The example supports the proposal that an adequate semantics must make modal evaluation sensitive to

information states, not only to worlds. The conclusion is not that worlds play no role, but that information states must also figure in modal evaluation (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The stated inference runs from sequential conjunction, consistency-testing might, and the order contrast to the demand for information-state-sensitive evaluation, not only evaluation by worlds. The example's force is limited to that support. It supports the proposal's claim, but it does not by itself establish that every epistemic modal behaves this way. Accordingly, the conclusion remains a requirement on an adequate semantics, supported by the described commitments and contrast, rather than an independently established result about all epistemic modals (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The route from the commitments to the contrast can be stated without extending either one. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the two features under consideration. For this argument, the two features are a sequential interpretation of conjunction and a consistency-test treatment of might. In the example, information that it is not raining is added before the might-information; the stated consistency result concerns that first order. In the opposite order, there is no problem (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The supplied contrast describes whether the might-information is consistent after the not-raining information is added and in the opposite order. In the example, adding not-raining information before the might-information raises a consistency problem; the opposite order presents no problem. Saying that order matters in discourse summarizes this difference, without replacing it with a claim about other sequences or other modal expressions (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The answered question is affirmative: the might-operator is treated as a consistency test on an information state, and adding information in a different sequence changes whether the might-claim remains consistent. This supports information-state-sensitive evaluation rather than evaluation by worlds alone. This is the supplied connection between the sequential interpretation and the contrast. The order effect is thus presented as relevant to modal evaluation through the way the consistency test applies to information added in sequence (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The stated commitments and contrast support the requirement that modal evaluation be sensitive to information states, not only to worlds. The conclusion is the demand on an adequate semantics; the stated premises and their connection support that demand. It does not follow here that worlds have no role, nor does the example by itself establish that every epistemic modal behaves this way. The support remains conditional on the commitments and the described contrast, and its conclusion remains the specific adequacy requirement supplied (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The inference can be tracked without enlarging either premise. For this argument, the two features are sequential conjunction and consistency-testing might; this sentence restates them without adding a rule. In the example, the not-raining information is added before the might-information; the resulting

consistency contrast is with the reverse order, which presents no problem. The commitments and contrast connect sequential information and consistency testing to the difference between these two orders (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The stated commitments and contrast support the demand that modal evaluation be sensitive to information states, not only to worlds. The conclusion is supported by the commitments and the contrast, rather than presented as an independently established premise. Its scope remains the demand supplied: the example supports information-state sensitivity, but does not by itself establish that every epistemic modal behaves this way (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

5. Force and Limits of the Support

The central conclusion is that an adequate semantics of epistemic modals must make modal evaluation sensitive to information states, not only to worlds. The stated support combines the commitments about conjunction and might with the contrast between the two orders of adding information. Dynamic semantics gives conjunction a sequential interpretation and treats the might-operator as a consistency test (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The contrast is specific. In the example, information that it is not raining is added before the might-information; the stated consistency result contrasts with the reverse order, which presents no problem. The contrast is summarized by the claim that order matters in discourse (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). It is this difference between the specified sequences—not a claim about every possible order or every modal—that the support invokes.

The two commitments explain why that difference bears on modal evaluation. For this argument, conjunction is interpreted sequentially and might is treated as a consistency test; these are the two features under consideration. Under those commitments, the question for a might-claim is whether it remains consistent with the information state against which it is assessed (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). When the sequence of information changes, the consistency outcome in the stated example changes as well: adding the not-raining information first leaves it no longer consistent with the might-information, whereas the reverse order presents no problem (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

Thus the example supports information-state-sensitive evaluation: sequential addition affects the information state, and the might-test is one of consistency with that state (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). This is the direction of support. Given the stated commitments and order contrast, an adequate semantics must make modal evaluation sensitive to information states, rather than relying on worlds alone (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The scope of that conclusion should remain exact. The demand is sensitivity to information states, not only to worlds. Nor does the particular order effect by itself establish that every epistemic modal behaves in this way. The example supports the proposal’s claim, but the support is limited to that role: it illustrates how consistency testing against sequentially updated information makes order relevant to modal evaluation (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

Accordingly, the claim is conditional on the stated premises and their supplied connection. If conjunction is interpreted sequentially, might tests consistency, and the described order contrast holds, then the contrast supports the demand that an adequate semantics make modal evaluation sensitive to information states, not only to worlds (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). The conclusion remains a requirement supported by these commitments and this example, not an independently established universal claim about epistemic modals.

The limit on the example's support is important to how the conclusion is stated. The order contrast supports information-state-sensitive modal evaluation: the might-claim is tested for consistency with information added in sequence. But the example does not, by itself, establish that every epistemic modal behaves in this way. The conclusion is therefore the supplied demand on an adequate semantics, not a universal generalization about all epistemic modals (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

This distinction preserves both parts of the support. In the example, information that it is not raining is added before the might-information; the stated consistency contrast is with the opposite order, which presents no problem. That is the specified way in which order matters in discourse (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). On the other side, the reach of this contrast is not extended beyond its stated role. It shows how the specified sequences differ; it does not establish that every epistemic modal has the same behavior. The answered question is thus affirmative about the example as evidence for information-state sensitivity, while retaining this stated limit on what the evidence establishes (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The same care applies to the semantic commitments. Dynamic semantics gives conjunction a sequential interpretation and interprets the might-operator as a consistency test (Groenendijk, Stokhof & Veltman 1996, PDF p. 18). The commitments and order contrast support the conclusion that modal evaluation must be sensitive to information states, not only to worlds. They do not turn the example into a claim about every modal, and the conclusion does not need that wider claim in order to state its demand. Its content is that an adequate semantics of epistemic modals must make information states matter to evaluation (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

Accordingly, the relevant inference remains conditional on the supplied commitments and contrast. If the stated commitments and order contrast are taken as support, they support information-state-sensitive evaluation, not evaluation by worlds alone. This neither claims that the premises have been independently established here nor adds a conclusion about other sequences or modalities. It restates the direction of the provided support: from the commitments and the specified order effect to the requirement for an adequate semantics (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).

The demand is sensitivity to information states, not only to worlds. The conclusion requires modal evaluation to be sensitive to information states, not only to worlds. The stated commitments and order contrast support information-state-sensitive modal evaluation. Its limit is equally precise: this support does not by itself establish that every epistemic modal behaves in the same way. Keeping the

requirement and its limit together preserves the conclusion's scope: information-state-sensitive evaluation is the demand supported here, while a universal claim about all epistemic modals is not (Groenendijk, Stokhof & Veltman 1996, PDF p. 18).
